REC'D 10 JUN 1999	
WIPO	PCT

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Request for grant of a patent

(See the notes on the back of this form. You can also get an explanatory leaflet from the Patent Office to help you fill in this form)

1. Your reference	27.42.67986/000		
2. Patent application number (The Patent Office will fill in this part)	9809974.0		
3. Full name, address and postcode of the or of each applicant (underline all surnames)	Carbontech Holding AS Hjorteveien 41 5046 Rådal Norway		
Patents ADP number (if you know it)			
If the applicant is a corporate body, give country/state of incorporation	Norway	7433899001	
4. Title of the invention	Process		
5. Name of your agent (if you have one)	Frank B. Dehn & Co.		
"Address for service" in the United Kingdom to which all correspondence should be sent (including the postcode)	179 Queen Victoria Street London EC4V 4EL		
Patents ADP number (if you know it)	166001		
6. If you are declaring priority from one or more earlier patent applications, give the country and the date of filing of the or of each of these earlier applications and (if you know it) the or each application number	Country	Priority application number (if you know it)	Date of filing (day / month / year)
7. If this application is divided or otherwise derived from an earlier UK application, give the number and the filing date of the earlier application	Number of earlier application	Date of filing (day / month / year)	
8. Is a statement of inventorship and of right to grant of a patent required in support of this request? (Answer 'Yes' if: a) any applicant named in part 3 is not an inventor, or b) there is an inventor who is not named as an applicant, or c) any named applicant is a corporate body. See note (d))	Yes

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s) of the form. Any continuation sheet should be attached to this form.
- If you have answered 'Yes', *Patents Form 7/77* will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Process

The present invention relates to methods for producing solid carbonaceous materials and hydrogen-rich gases, methods of combustion, reactors for the same and use of such reactors.

Natural gas and several of its derivatives are most commonly used for energy purposes, by conversion to heat and electricity. With few exceptions, this conversion is started with a combustion process, where the so-called heating value of the fuel gas is released by converting the hydrogen and the carbon in the fuel gas into water (vapour) and CO_2 . The oxygen necessary to perform this reaction is derived from the atmosphere which consists of 21% oxygen and 79% nitrogen.

Natural gas normally contains more than 80% methane and thus combustion may be represented by the overall reaction equation:

This combustion provides a heating value of 50000kJ/kg of methane. The combustion of for example CH_4 includes as many as 400-500 elementary reactions. However, only a few of these lead to a significant energy release in terms of heat.

Viewed in a simplistic way, the carbon is converted during combustion as follows:

If oxidation is divided into two steps as indicated above, the heat related to the formation of CO is only moderate causing only a small temperature increase. However, a large temperature increase is associated with the formation of CO_2 . Thus the main heat release in hydrocarbon flames is associated with the formation of CO_2 .

and H_2O .

When combustion of hydrocarbons take place a lot of intermediate species are formed, most of which are combusted before the products leave the flame so that in general the final products which result are in the form of CO_2 and H_2O .

In flames, soot may also be formed. The formation of soot takes place on the fuel rich side of the flame and results as a consequence of heating the fuel. Soot is a hydrocarbon with 1-3% by weight of hydrogen and is a polybenzenoid molecule. It has been suggested that it may have a structure similar to $\text{C}_{40}\text{H}_{16}$.

Soot formation from the gas phase includes a dehydrogenation process, similar to cracking and/or pyrolytic decomposition, which probably produces the product C_2H_2 before being built up into a larger molecule by virtue of several thousand steps. However, in macroscopic terms, the soot formation process may be viewed as a two step process, namely the formation of a nucleus and then particle formation. The soot particles look like small spheres that may be agglomerated into clusters like grapes. The individual spheres have a diameter in the order of 10-100 nanometres.

In normal combustion of a hydrocarbon fuel, the fuel is introduced into the combustion chambers or burner systems in the form of jets or fuel sprays, or in other cases as a mixture between this fuel and the oxidizer, which is usually oxygen from the air. Usually two types of flames may be formed depending on the types of burner systems which are employed.

Diffusion flames occur when the fuel and oxygen are mixed on both the macro and micro, but not molecular scale through diffusive processes. Since combustion only occurs when reactants are mixed on a molecular scale, this gives rise to laminar or turbulent flames. Thus, the so-called thermal reactions resulting from the high temperatures of the laminar and/or turbulent flames take

place only in localized regions such as thin sheets, vortex structures or similar which lie at the interface between the fuel and the oxygen. Generally the so-called thermal reactions at these sites are very fast and the temperature in the reaction zone is very high.

Pre-mixed flames occur when the fuel and oxygen are pre-mixed on a molecular scale. Generally a propagating flame is formed which has associated with it a flame velocity which refers to the propagating velocity of the flame. Such flames may be fuel-rich or fuel-lean. Many combustion devices utilize lean pre-mixed combustion as the reaction temperature is low thus leading to a reduced formation of NO_x (which is formed from N_2 in air) since reactions leading to NO_x formation are generally slow and strongly temperature dependent. In both of the above types of flames the same chemical reactions occur, albeit at different sites, but the influence on the products of the different reactions may vary.

In an ordinary combustor or burner, only a small fraction of the carbon is converted into soot and the soot burns away before the product leaves the flame. In some cases such as in lean premixed flames no soot is formed. In fires with big diffusion flames, where very fuel-rich structures are heated, large amounts of soot are produced. Sometimes 10-20% of the carbon in the fuel forms as soot which is not burnt off.

However, a major disadvantage with this combustion is the production of CO_2 which is detrimental to the environment. Furthermore, the soot-like material which forms, which has potential uses in a number of industrial applications is lost.

US-5527518 (Kvaerner Engineering AS) describes a method of pyrolytic decomposition of natural gas (or methane) which results in the production of a hydrogen-rich gas by the use of a plasma torch which heats the hydrocarbon fuel to about 1600°C . Instead of the production of CO_2 , carbon black, which may contain some

hydrogen, is produced. This reaction is performed in the absence of oxygen except in reactions to modify the properties of the carbon black which has already been produced.

It has now surprisingly been found however, that at moderate detriment to the heating value per kg of fuel gas, harmful emissions of CO₂ may be reduced by conversion of the carbon content of the fuel into a solid form of carbon which has useful industrial applications.

This is achieved by manipulation of the above mentioned reaction scheme by using a controlled amount of oxygen in the system and by using a combustion process, which may be separated into 2 separate stages, coupled with pyrolytic decomposition.

By controlling the amount of oxygen in the system, the equation may be rewritten as:

In the above reaction, while hydrogen is converted to water, carbon is decomposed from the fuel and forms as a solid material similar to soot. As a consequence, very little or no CO₂ forms. Such processes are achievable and still retain more than 50% of the original heating value. However in most cases it is realistic to expect that some carbon will react to form CO₂ and some will produce solid carbon, depending on the operating conditions and the reactor vessel design. Thus for example, a practical, readily or easily achievable reaction may be written as:

This reaction would provide a heating value of 40000kJ/kg fuel gas, produce 50% less CO₂ and produce solid carbon at an amount of 0.375kg/kg methane. Thus a significant reduction in CO₂ emissions may be achieved with only a 20% reduction in heating value.

During the course of the above described reaction, unlike known reactions, significant amounts of solid carbon and hydrogen-rich gas are produced. This is achieved through incomplete combustion of the feed stock by control of the amount of oxidizer, e.g. pure oxygen, which is introduced into the system thus preventing continued combustion such that these products may be collected. The hydrogen-rich gas may then be combusted immediately or after collection to provide an energy source.

Thus, viewed from one aspect, the present invention provides a method of producing solid carbonaceous C_xH_y , wherein x and y are the average number of carbon and hydrogen atoms respectively and the ratio of x:y is greater than 2.5:1, wherein a hydrocarbon fuel is heated with oxygen at a C:O ratio greater than 1:3, preferably 1:2 (e.g. 1:0.2) to a temperature of at least about 1000°C whereby to effect incomplete combustion and pyrolytic decomposition of said hydrocarbon fuel.

Preferably the value of x in the x:y ratio exceeds 40, leading to H_y of less than 1-3% by mass in C_xH_y .

As referred to herein, "hydrocarbon fuel" refers to any commercially or readily available hydrocarbons which are gaseous at a temperature of 20°C and a pressure of 1 bar and which are susceptible to pyrolytic decomposition and/or combustion. This includes the fuel used to create the flame (referred to herein as the "flame fuel" or "flame gas") which may be the same or different to the bulk feed stock fuel. Particularly preferred is natural gas which is composed mainly of methane. Other appropriate hydrocarbons include acetylene (C_2H_2) and propane (C_3H_8). "Fuel gas" as referred to herein indicates the hydrocarbon fuel and any associated trace carrier gas, e.g. air, oxygen, nitrogen, CO_2 etc. Trace amounts of oxygen which may be present with the hydrocarbon fuel, such as in air do not constitute the oxidizer required for performance of the invention. This

oxidizer is supplied in a controlled and precise manner.

Thus, the present method allows the production of a solid carbonaceous product containing 20% or more, preferably 50% or more, for example at least 80% of the carbon introduced into the system, by subjecting the hydrocarbon fuel to thermal reactions with limited combustion achieved by the use of restricted amounts of an oxidizer. Combustion of the hydrocarbons of a portion of the fuel gas (ie. that portion which is the flame gas, which may be the same or separate to the remaining feed stock) produces hot combustion products which then serve to heat the remaining feed stock producing the reactions required for solid carbon/hydrogen-rich gas production.

Preferably the method is performed by pre-heating the fuel gas to between 600 and 800°C, for example approximately 600°C and passing said fuel gas into a reactor. By raising the temperature of the gas, the hydrocarbon reaches a temperature close to the temperature at which pyrolytic decomposition may occur, but is not heated to a temperature where it will actually begin to decompose in the fuel stream prior to entering the reactor.

Once in the reactor, said fuel gas is rapidly heated to a temperature of between about 1000 and 2000°C (when measured locally) for between 0.1 and 10 seconds by interspersing said gas with air- or oxygen-assisted hydrocarbon flames (which may be produced by the hydrocarbons of the fuel gas) wherein the heat of the combustion products causes localized heating resulting in pyrolytic decomposition. Conveniently, the reactor is operated at a pressure of between 0.1 and 150 bars.

The atmosphere in the reactor is composed solely of the fuel gas (including the flame fuel), the oxidizer (with any carrier gas) and the combustion and/or decomposition and/or decomposition products (e.g. solid carbon and hydrogen-rich gases). No other compounds are included in the reactor.

In one of its simplest embodiments, the fuel gas is introduced into the reactor where it is interspersed with oxygen and/or air in a controlled manner and ignited thus causing local combustion limited by the amount of oxygen which is introduced. The periphery of the flames which intersperse with the remainder of the fuel gas contains the hot combustion products thereby causing pyrolytic decomposition of adjacent molecules of the hydrocarbon fuel.

Due to the limited amount of oxygen which is employed as oxidizer, the oxidizer is used up during the combustion reaction. Thus, soot formed in the reaction does not burn due to the absence of an oxidizer. However, when using the combustion products to heat the fuel gas, oxygen may be produced by decomposition of fractions of the combustion products H_2O and CO_2 . To avoid this, heating should be performed as rapidly as possible as mentioned above to prevent burning of the soot. This stimulates nucleus formation resulting in soot formation.

As mentioned above, said hydrocarbon flame may be produced by a hydrocarbon which is the same or different to the hydrocarbon-containing fuel gas, for example the hydrocarbon of the flame may be acetylene. The hydrocarbon of the fuel gas may be selected to alter the yield of solid carbon. For example, an acetylene or hydrogen flame may be used in preference to a methane flame due to the higher temperatures which the former achieves which results in higher solid carbon production.

Combustion products which are of a sufficient temperature to heat the fuel gas may be produced in different ways. For example, a burner system may be used which is associated with, optionally external to, the reactor. Combustion in the burner system may be achieved by reaction between a fuel specially introduced into the burner and an oxidizer, for example oxygen from air to produce a flame. Oxygen may be separated from the

nitrogen in air and the nitrogen itself may be used in conjunction with other products of the methods described herein in chemical processes.

Preferably, the burner or burner-like system utilizes pure or nearly pure oxygen (with a moderate admixture of nitrogen, preferably with a O:N ratio greater than 1:1). The burner fuel (equivalent to the flame fuel) which is used for combustion may be the fuel corresponding to the fuel gas, or a different fuel, or more preferably may be the hydrogen-rich gas produced from the reaction of the invention which is provided to the burner system via an outlet of the reactor. The fuel which is used must be able to achieve temperatures of 2000°C or more. The use of the hydrogen-gas is preferred to avoid excessive production of CO₂. Furthermore, reaction of hydrogen with oxygen leads to very high temperatures.

Localized heating of the hydrocarbon-containing fuel gas using the hot combustion products of the burner may be achieved by mixing the combustion products with the fuel gas such that rapid and temporary heating (ie. 0.1 to 10 seconds) of the fuel occurs. In the case in which a burner system is used, the C:O ratio referred to herein refers to all carbon and oxygen atoms involved in the reaction and thus includes those involved in the reaction in the burner.

Flames which intersperse said fuel gas may be achieved by the use of a turbulent flame. Such flames are effective due to their ability to cause localized heating of the fuel gas, thus generating the high temperatures at the flame/fuel interface required for solid carbon formation. The burner system is preferably designed in such a way that the momentum of the combustion products (e.g. created by using an oxygen-assisted flame) may be utilised to perform a rapid mixing with the feed-stock or fuel gas. Similarly, the fuel gas may be brought into contact with the combustion products

by utilising and enhancing the momentum of the fuel gas. To achieve this aim, the interior of the reactor for performance of the method of the invention may be designed to allow counter flow, co-flow, cross flow or a combination thereof, of the fuel gas and the hot combustion products of the burner system.

In a counter-flow version of the invention, the oxidizer, the flame fuel and/or the hot combustion products from the burner system may be introduced through nozzle-like inlet port at very high velocity (typically 20-200m/s), in an opposite direction to the fuel gas, thus allowing the oxygen or hot combustion products to penetrate into the fuel gas, creating very hot fine structures, such that the formation of the solid carbonaceous material takes place in a large part of the fuel gas volume. The outlet of the reactor should be arranged to optimize the interaction of the fuel gas with the hot structures.

Alternatively, the oxidizer, the flame fuel and/or the hot gases are introduced through nozzles which surround the outlet, thus the fuel gas necessarily encounters the hot flames.

In the above described cases, the fuel gas may itself be introduced into the reactor in such a way to form a vortex flow structure.

Both the co-flow and cross-flow versions of the invention utilize the same mechanisms for their production, namely creation of shear forces by the interactions between the high velocity of one or more of the oxidizer, combustion products, flame gas or fuel gas, to create inter-mixing of the heated structures in the fuel gas. To achieve this effect, the inlet ports may be designed in such a way to create cyclone-like flow in the reactor.

In all cases, the mixing is designed such that rapid mixing may be achieved. After mixing, the peak of high local temperature disappears such that the temperature of

the product which leaves the reactor is homogenous and preferably has a temperature in the order of 1000°C.

Alternatively, the interior of the reactor may be designed in such a way that no burner is present, but the fuel gas and oxidizer is mixed and ignited, such that thermal reactions between the fuel gas and the oxygen takes place in a localized fashion leading to temperature peaks exceeding 2000°C. One way to achieve this is to create turbulent structures that will contain the thermal reactions. The oxygen thereby completely or nearly completely reacts to form CO_2 and H_2O . The amount of carbon in the fuel converted to CO_2 is small since the average heating of the fuel gas is moderate and of the magnitude of 1000°C, while the reacting structures locally achieve a much higher temperature and the amount of oxidizer which is available is limited.

The above is preferably achieved by supplying the oxidizer to the reactor in the form of pure oxygen or nearly pure oxygen, but may also be achieved if the oxygen includes a moderate admixture of nitrogen.

Thus, viewed from a preferred aspect, the present invention provides a method of producing a solid carbonaceous product wherein a hydrocarbon fuel is heated with oxygen at a C:O ratio greater than 1:3, e.g. equal or greater than 1:2, said method comprising at least the steps of pre-heating the fuel gas containing said hydrocarbon fuel and passing said fuel gas into a reactor in which said fuel gas is rapidly heated to a temperature of between about 1000 and 2000°C for between 0.1 and 10 seconds by interspersing said gas with air- or oxygen-assisted hydrocarbon flames to obtain localized heating whereby to effect partial pyrolytic decomposition.

The C:O ratio corresponds to the ratio of the total carbon and total oxygen admitted to the reactor (including those admitted to the burner which may be external to the reactor), wherein the latter may be in the form of O_2 , H_2O , CO_2 etc. As mentioned above, the C:O

ratio is preferably significantly greater than 1:2 and thereby the oxygen which leaves the reactor by the outlet is in the form of H_2O and most of the hydrogen is in the form of H_2 .

The solid carbonaceous product produced by this method may be collected continually or intermittently during its production or at the end of the reaction. In cases where combustion of the hydrogen-rich gases which have been produced is to be performed, if this combustion is performed in a separate stage, the carbon may be collected prior to its initiation. Separation of the solid carbon may be performed by a cyclone system or filter-like or scrubber system, after which the solid carbon is cooled. However, if the production of solid carbon, hydrogen-rich gases and the latter's combustion is all performed sequentially or simultaneously in the same reactor, then the carbon black may be collected during or after the reaction.

The solid carbon thus formed has particular industrial applications and forms a further aspect of the invention. For example, the carbon may be used as an admixture in solid materials to modify the physical properties of the materials, such as their strength, thermal response, flexibility or wear.

The physical properties of the carbonaceous material may be modified by altering the operational conditions of the reactor. For example, this may be achieved by adjusting the inlet feeds to the reactor and/or reactor pressure, or by modifying the interior structure of the reactor such that the time scales of the heated structures are changed. This may be achieved for example by increasing the momentum of the oxidizer, flame gas, fuel gas and/or combustion products introduced into the reactor. This may be achieved by increasing the flow rate of one or more of the above components or by reducing the input port or nozzle area and maintaining the same flow rate.

The soot-like carbon may be formed into materials such as carbon fibres, tubes, whiskers, spheres, shells or to fill particles or used in the production of materials such as printer's ink, technical rubber, carbon-containing solid materials such as pipe-materials and electrodes or as an additive such as to increase the strength of other materials such as metal, concrete etc.

The above described method also produces hydrogen-rich gas which is a combustible fuel which may be used as an energy source.

The present invention additionally thus provides a method of producing a hydrogen-rich gas with a H:C ratio on atomic basis equal to or exceeding 20:1, (ie. equal or less than 20% of the carbon in the feed stock is converted to CO₂, e.g. about 50:1) and a H:O ratio greater or equal to 5:1 (e.g. about 10:1), wherein a hydrocarbon fuel is heated with oxygen at a C:O ratio greater than 1:3, preferably greater than or equal to 1:0.2, to a temperature of at least about 1000°C whereby to effect partial pyrolytic decomposition of said fuel.

In the above method, the H₂O which is produced is gaseous at the temperatures involved and is thus considered to form part of the hydrogen-rich gas.

As mentioned in connection with the solid carbon, this may be harvested during and/or after the reaction which produces it.

The energy produced by combustion of the hydrogen-rich gases of the invention may be used for any conventional processes requiring energy. Thus for example, combustion of the hydrogen-rich gases may be linked to a gas turbine combustor or other machinery by appropriate modification of the reactor pressure for connection with associated machinery. The reactor and the interior of the reactor are preferably designed and operated at pressures such that utilization of the hydrogen-rich gas in energy systems may be readily facilitated and not require compression of the gas before

it is used.

Such systems may have as their main purpose the use of solid carbon produced according to the methods of the invention, for example systems in which the solid carbon is formed into pellets, blocks or as bulk material. Alternatively, the systems may be designed to form fullerenes (pellets), diamonds or monodisperse spheres of uniform size. The gas may also be used as fuel in a furnace such as in steam raising furnaces, glass furnaces, metallurgical furnaces or similar. Advantageously, the above methods produce only small amounts of CO₂ and offer environmentally friendly alternatives to conventional processes.

The hydrogen-rich gas may also be used to provide the fuel for the flame used in the method of the invention. Alternatively, the heat of the gas exiting from the reactor may be employed, for example to pre-heat the fuel gas, thus allowing conservation of energy.

The invention thus further provides a method of combustion wherein the hydrogen-rich gas produced according to the invention is combusted. This combustion may be performed on the hydrogen-rich gas to produce energy which may then be utilized or may form an integral part of a chemical, metallurgical or similar process.

Optionally, the energy evolved in the first stage of the reaction, ie. pyrolytic decomposition and combustion in the flame, may be utilized for the energy-requiring processes contemplated above. It will be appreciated that under certain circumstances, all or a part of the energy evolved during the first or second stage of the reaction may be recycled for use in initiating or sustaining these reactions.

The hydrogen-rich gas may also be used in chemical processes other than combustion to produce hydrogen-containing chemicals. When the oxidizer used in the above reaction is in the form of oxygen which has been separated from nitrogen in air (as described above), the

nitrogen thus produced may be used in processes with the hydrogen-rich gas produced above to produce nitrogen-hydrogen compounds such as NH_3 or other compounds including nitrogen and hydrogen and other elements. In this respect, it will be appreciated that in reactions described above, sufficient amounts of hydrogen-rich gas are produced to ensure that nitrogen which is separated from air to yield the oxygen which is used in the reaction will be fully utilized to produce NH_3 with some hydrogen-rich gas remaining.

Reactors appropriate for performance of the invention form a further aspect of the invention. Reactors of the invention comprise at least: one or more inlet ports to carry the fuel gas into the reactor cavity, through which the oxidizer may also be carried, and one or more outlet ports, optionally with a capture chamber, through which evolved gases of the reactions may leave the reactor. Reactors are required to sustain temperatures required for performance of the above methods, ie. greater than about 2000°C and pressures of 0.1 to 150 bars and thus should be manufactured from heat resistant steel or similar and equipped with heat resistant internal cladding and insulation.

To allow ignition of the fuel gas to produce flames which intersperse with the remaining fuel gas, a source of ignition is provided which may be external to or within the reactor (or external to or within a chamber within the reactor).

In instances in which the flame (or its combustion products), flame fuel and/or the oxidizer is provided separately to the fuel gas, one or more further inlet ports may be provided, for example a burner system may be provided which produces a flame and allows combustion products to enter the reactor. In this way, combustion is completed prior to contact with the remaining feed stock.

Thus, viewed from a further aspect the present

invention provides a reactor for performance of the methods of invention comprising at least: one or more inlet ports allowing entry of the fuel gas into the reactor cavity, one or more outlet ports through which evolved gas may leave the reactor and a source of ignition whereby to effect partial combustion of hydrocarbons introduced into said reactor or associated burner.

Said burner may be external or internal to the reactor cavity or chamber. In both cases, combustion products enter said reactor chamber through one or more reactor inlet ports. In the case of an externally arranged burner, said burner is connected to said one or more inlet ports via one or more inlet tubes. Where a distinct reactor chamber is present in the reactor cavity, appropriate inlet/outlet tubes or ports are provided for communication across the space between the reactor walls and the reactor chamber.

As mentioned previously, appropriate mixing of the combustion products and the fuel gas may be achieved by introducing the flame or combustion products (if a burner is used), the flame gas, the oxidizer and/or the fuel gas through nozzle-like inputs or ports at a velocity of 20-200m/s into (preferably in an opposite direction) one or more of the afore-mentioned gases, for example in an opposite direction to the fuel gas. These nozzles represent inlet ports and may replace or supplement existing inlet ports. They may be arranged in various positions within the reactor, or arranged in appropriate patterns, for example around the reactor outlet. Thus, the use of multiple inlet ports for the entry of fuel gas, flames, combustion products, flame gas, and/or oxidizer, of a diameter suitable to allow interspersion with other elements of the reaction when operated at an appropriate flow rate, is preferred.

Preferred embodiments of the invention will now be described with reference to the Figures in which:

Figure 1 shows a reactor for use according to the invention in which the oxidizer is admitted to the reactor through a separate inlet port;

Figure 2 shows a reactor for use according to the invention in which internal heating is provided by an integral burner system with separate flame fuel and oxidizer supplies in which the fuel may be provided by the fuel gas, the hydrogen-rich gas which is produced or a separate fuel source;

Figure 3 shows a reactor similar to the reactor shown in Figure 2 but with an external burner system;

Figure 4 shows a reactor fitted with a simple control system; and

Figure 5 shows how the reactors may be coupled to energy or gas turbine systems.

Figure 1 shows a reactor with an internal reactor chamber (1) within the reactor. The reactor additionally comprises a fuel inlet port (2), an oxidizer inlet port (3) and an outlet port (4). These inlet ports are appropriately connected to the reactor chamber (1) to allow entry of the media carried through the inlet/outlet ports, e.g. by reactor chamber inlet ports (not shown) or by the use of a chamber which is not sealed, e.g. a cylinder-shaped chamber with unsealed ends. The reactor chamber may be associated with the reactor cavity inner walls or may be separate therefrom allowing the passage of gases/solid between the reactor cavity inner wall and the reactor chamber outer wall, e.g. via inlet/outlet tubes or ports.

A source of ignition (5) is provided to ignite hydrocarbons in the reactor and may be positioned exterior of or within the reactor chamber. A heat source (6) is arranged in sufficient proximity to the fuel inlet port (2) to allow heating of the fuel gas. The reactor is insulated (7) and heat recovery may be achieved in an appropriate manner using an energy capture means (8),

such as by heating H_2O containing structures or other heat absorbing medium such as oil, liquid metal, gas, air or other appropriate substance. A further outlet port (9) may be provided, in this case exterior to the reactor chamber, for collection of the solid carbon material by use of a carbon removing device (10) such as a cyclone, filter, scrubber, scraper or electrical/mechanical precipitator.

In this embodiment, fuel gas is passed into the reactor through inlet port (2) after it has been pre-heated by the heating means (6). The pre-heating means may be provided by the outlet gas from the reactor. Oxidizer then enters the reactor and chamber via inlet port (3) and mixes with the feed stock (fuel gas) to produce a combustible mixture. This is ignited by the ignition means (5) resulting in combustion to the extent that the presence of the oxidizer allows. The hot combustion products are then interspersed as described previously by the action of shear generated turbulence at the interface between the fuel gas and the high velocity oxidizer (e.g. oxygen), hot combustion products or flames into the areas of the fuel gas which have not been combusted to produce thermal reactions at the interface of the combustion product and the unspent fuel leading to the production of solid carbon. This carbon may be collected by the carbon removing device (10) and collected through the outlet port (9). Hydrogen-rich gas leaves the reactor through outlet port (4) and may be utilized for heating the fuel gas or in a different energy requiring system. Energy produced (in the form of heat) in the reactor during the combustion and decomposition processes may be collected through appropriate energy capture means (8).

In Figure 2, the oxidizer inlet port (3) and source of ignition (5) of Figure 1 is replaced with a burner (11) which is fed via an inlet port (12) which carries the oxidizer and flame gas to the burner for ignition.

The burner includes an ignition means. The flame gas may be provided by a portion of the fuel gas, by the hydrogen-rich gas produced in the reactor or by the use of a separate fuel source. Similarly, in Figure 3, the burner (11) may be placed external to the reactor, and be connected thereto by an inlet port (3) and the fuel gas and oxidizer provided into the burner via inlet port (12).

Figure 4 shows a schematic representation of the reactors shown in Figures 1 to 3 in which various control valves are included. Thus, entry of the fuel gas may be controlled by flow control valve (1) into the reactor and by flow control valve (2) into a burner or point of ignition. Flow control valve (3) may be provided to control the flow of oxidizer into the reactor. As will be appreciated from the discussion herein, the amount of oxidizer which is introduced into the reactor is crucial and thus this valve is of particularly importance for controlling the reaction. Pressure control valve (4) may be used to control the release of the gas which is produced in the reactor. Filter (5) onto which the solid carbon is collected may be linked to the outlet port carrying the hydrogen-rich gas and the flow of carrier gas from the filter may then be controlled by a control valve (6).

Figure 5 shows how the energy produced in the 2-stage process of the invention may be used to power a gas turbine. In this case fuel gas is passed via port (1) into the reactor (2) and heated by the hot combustion products which enter the reactor at inlet port (3) produced by the combustion of a flame fuel and an oxidizer. The hydrogen-rich gas which exits at outlet port (4) is passed to a burner (5) where in the presence of air, which is compressed and provided via burner inlet port (5a), it is combusted. The combustion products exit the burner via outlet port (6) and are used to power a turbine (7) which in turn is used to generate

electricity.

Appropriate heat-exchange mechanisms may be employed, for example at (8) as shown in the previous Figures, at (9) to warm air to be passed into the burner and at (10) to capture the heat of exhaust gases.

Use of the above reactors for the production of the solid carbon or hydrogen-rich gas or for the production of energy form further aspects of the invention.
